Abstract: This paper proposes a control strategy that mitigates the cross contamination of H₂ and O₂ in a high-pressure alkaline electrolyzer, which consequently increases the supplied gases purity. In order to reduce the diffusion of gases through the membrane, the controller establishes the opening of two outlet valves based on the pressure of the system and the difference in liquid level between both separation chambers. Therefore, a multiple input - multiple output optimal controller is designed here. For this purpose, an available high-fidelity model was simplified in order to obtain a control-oriented model. The proposed controller was evaluated in simulation using the high-fidelity nonlinear model in a wide operating range and was compared with a pair of decoupled PI controllers. The resulting impurity of gases was below 1% in all cases.

Keywords: Hydrogen, alkaline electrolysis, H₂ purity, multivariable control

1. INTRODUCTION

The world economy is constantly expanding along with the demand for energy (IEA, 2019). Furthermore, the extensive use of fossil fuels, with the consequent emission of greenhouse gases, is widely accepted as a situation that needs to change. In this line, global impact studies and environmental protection policies have been formulated (Lux and Pfluger, 2020; Gorre et al., 2019). Around the world, solutions focused on renewable energy sources have been proposed in order to mitigate the emission of greenhouse gases due to the intensive use of fossil fuels. However, the ability to accumulate the excess of energy over long periods of time is needed in order to reach a high integration of renewable energy sources. A widely accepted idea is the use of hydrogen as an energy vector, known as the hydrogen economy, which would be an integral solution to produce, store and supply energy (David et al., 2019b; Wang et al., 2019).

Among all the methods of producing sustainable hydrogen, the alkaline electrolysis is presented as the most mature technology. Currently, there is a renewed interest in this technology due to its ease of connection to renewable energy sources (Mahlia et al., 2014). Commonly, the combination of electrolyzers, storage tanks and fuel cells is used as an energy buffer (Dawood et al., 2020). Alkaline electrolysis consists in the splitting of water to form H₂ and O₂ by applying an electric current. The electrolytic cell consists of a pair of electrodes and a membrane made of Zirfon™ that prevent gas mixing. One of the most important challenges of the alkaline electrolysis is the diffusion through this membrane driven by differences in concentration and pressure (Schulenbach et al., 2018).

Although the first cause of cross-contamination is inherent in the process and is related to the development of new membranes, the pressure differential can be mitigated by a suitable control design actuating over the outlet valves of both separating chambers.

Despite alkaline electrolysis is a mature technology, its mathematical modelling is still under development. Most models focus only on the cell-stack description but not in the entire system (Haug et al., 2017; Milewski et al., 2014; Hammoudi et al., 2012). Moreover, most of them describe the stationary regime and are built from empirical equations (Amores et al., 2014; Ulleberg, 2003; Hug et al., 1993). Recently, Sánchez et al. (2020) used a commercial software to model the entire system while the cell-stack is described by a semi-empirical approach. In the same direction, some of the authors of the current work have developed a Phenomenological Based Semi-empirical Model (PBSM) reported in David et al. (2019a, 2020). This model has the advantage of describing the dynamic phenomena and the evolution of all the electrolyser subsystems.

Furthermore, to the best of the authors’ knowledge, and also from the conclusions reported by Olivier et al. (2017), the design of controllers to solve the problem mentioned above seems to be not addressed yet in the literature. Therefore, the development of useful input-output models for control design is an open research topic (Olivier et al., 2017). In general, control objectives are completely focused on the management of the electrolyzer as an electrical consumer and producer of H₂ connected to a grid (Vivas et al., 2018; Galetzauer, 2013). Moreover, the control of the outlet valves could be found mentioned only by Schug (1998) in his description of a pilot plant. In his work,
2. HIGH-PRESSURE ALKALINE ELECTROLYZER

As previously mentioned, a proposed solution for energy storage is the combination of an electrolyzer, storage tanks and a fuel cell. In this way, the additional electrical energy produced in the power sources, so it is beyond the scope of this paper. Details on this topic can be found in Milewski et al. (2014); Sánchez et al. (2020); Speckmann et al. (2019). The limits imposed are \( L_{min} = 0.45 \) m, \( L_{max} = 0.5 \) m, \( T_{min} = 39.5 \) °C and \( T_{max} = 40.5 \) °C. Finally, during the start-up act the control actions \( u_{pump} \) and \( u_{RS} \) manage the activation of the injection pump, the refrigeration system pump and the radiator, respectively.

Finally, energy management, with the consequent control of the current-voltage relationship, is intrinsically related to the power sources, so it is beyond the scope of this paper. Details on this topic can be found in Milewski et al. (2014); Sánchez et al. (2020); Speckmann et al. (2019).

As previously indicated, in alkaline electrolysis, a pressure difference between both half-cells generates the gas crossover. Therefore, the control objective is to keep the liquid solution levels equalized in both SCs while \( \text{H}_2 \) and \( \text{O}_2 \) are delivered at a certain pressure. This objective is achieved act over two motorized outlet valves (MVO and MVH in Figure 1). The operating ranges for pressure \( p \) and electric current \( I \) are 0-7000 kPa and 10-50 A, respectively. It is important to note that this electrolyzer, with an electrode area of \( A_{cell} = 143 \) cm², works in a current density \( j \) range between 70-350 mA/cm² under the direct relationship

\[
j = \frac{I}{A_{cell}}. \tag{3}
\]

With the aim of having a suitable resolution in these wide operating ranges and considering the \( \text{H}_2 \) production

\[
L_{\text{H}_2} \leq L_{\text{min}} \quad \text{and} \quad L_{\text{O}_2} \leq L_{\text{min}} \Rightarrow u_{\text{pump}} = 1, \\
L_{\text{H}_2} \geq L_{\text{max}} \quad \text{or} \quad L_{\text{O}_2} \geq L_{\text{max}} \Rightarrow u_{\text{pump}} = 0, \tag{1}
\]

\[
T_{\text{H}_2} + T_{\text{O}_2} \geq 2 \ T_{\text{max}} \Rightarrow u_{\text{RS}} = 1, \\
T_{\text{H}_2} + T_{\text{O}_2} \leq 2 \ T_{\text{min}} \Rightarrow u_{\text{RS}} = 0, \tag{2}
\]

where \( L_{\text{O}_2}, L_{\text{H}_2}, T_{\text{O}_2} \), and \( T_{\text{H}_2} \) are the liquid solution levels and temperatures in \( \text{O}_2 \) and \( \text{H}_2 \) SCs, respectively. These variables are measured by the transmitters LT1, LT2, TT1 and TT2, respectively (see Figure 1). The limits imposed are \( L_{\text{min}} = 0.45 \) m, \( L_{\text{max}} = 0.5 \) m, \( T_{\text{min}} = 39.5 \) °C and \( T_{\text{max}} = 40.5 \) °C. Finally, the control actions \( u_{\text{pump}} \) and \( u_{\text{RS}} \) manage the activation of the injection pump, the refrigeration system pump and the radiator, respectively.

High-pressure alkaline electrolyzers can supply gases at a storage pressure, dispensing with the use of compressors. However, cross-contamination, i.e., the concentration of \( \text{O}_2 \) in the \( \text{H}_2 \) stream and vice versa, increases with pressure, then special attention is required in operation due to safety and quality issues.

Figure 1 shows the piping and instrumentation of a high-pressure alkaline electrolyzer prototype. The components of this system are:

- a pressurized tank (PT) that contains a pack of 15 alkaline electrolytic cells;
- two independent KOH solution circuits with recirculation pumps;
- two gas separation chambers (SC) where the produced gas is split from the liquid KOH solution;
- two heat exchangers for both circuits (HEO and HEH);
- a water injection pump that periodically replenishes the consumed water;
- two outlet lines controlled by two motorized valves (MVO and MVH) connected to storage tanks; and
- an equalization line that connects both bottoms of the SCs.

A detailed description of this system is presented in David et al. (2019a, 2020).

As mentioned in the Introduction, the main objective of an alkaline electrolyzer is to separate water to form \( \text{H}_2 \) and \( \text{O}_2 \) by applying an electric current \( I \). In this process, it is highly important to minimize the diffusion through the membrane caused by differences in both concentration and pressure. Up to 2% of \( \text{H}_2 \) in the \( \text{O}_2 \) stream is widely accepted as a limit, taking into account that the lower explosive limit of \( \text{H}_2 \) is 4%. Additionally, \( \text{H}_2 \) and \( \text{O}_2 \) gases must be delivered at high pressures in order to avoid the use of compressors. Since gas purity decreases with higher pressures, it is expected to increase the possible operating pressure preventing contamination with a suitable control strategy.

2.1 Control scheme

An alkaline electrolyzer requires several control loops for an efficient and safe operation. The control of both the refrigeration system and the make-up pump ensures a safe operation of the electrolyzer. Whereas, the \( \text{H}_2 \) production is controlled by the outlet valves. This paper is focused on the latter. A brief description of the other loops is described next.

The refrigeration system and the make-up pump are controlled independently by hysteresis cycles. These control loops, whose designs are not going to be treated in this paper, are defined by the following sets of constraints:

\[
L_{\text{H}_2} \leq L_{\text{min}} \quad \text{and} \quad L_{\text{O}_2} \leq L_{\text{min}} \Rightarrow u_{\text{pump}} = 1, \\
L_{\text{H}_2} \geq L_{\text{max}} \quad \text{or} \quad L_{\text{O}_2} \geq L_{\text{max}} \Rightarrow u_{\text{pump}} = 0, \tag{1}
\]

\[
T_{\text{H}_2} + T_{\text{O}_2} \geq 2 \ T_{\text{max}} \Rightarrow u_{\text{RS}} = 1, \\
T_{\text{H}_2} + T_{\text{O}_2} \leq 2 \ T_{\text{min}} \Rightarrow u_{\text{RS}} = 0, \tag{2}
\]

where \( L_{\text{O}_2}, L_{\text{H}_2}, T_{\text{O}_2} \), and \( T_{\text{H}_2} \) are the liquid solution levels and temperatures in \( \text{O}_2 \) and \( \text{H}_2 \) SCs, respectively. These variables are measured by the transmitters LT1, LT2, TT1 and TT2, respectively (see Figure 1). The limits imposed are \( L_{\text{min}} = 0.45 \) m, \( L_{\text{max}} = 0.5 \) m, \( T_{\text{min}} = 39.5 \) °C and \( T_{\text{max}} = 40.5 \) °C. Finally, the control actions \( u_{\text{pump}} \) and \( u_{\text{RS}} \) manage the activation of the injection pump, the refrigeration system pump and the radiator, respectively.

Given the lack of control strategies designed for such systems and, in particular, those strategies based on suitable and reliable models properly obtained for control tasks, the main contribution of this paper is twofold. First, from a well-established nonlinear model considering the dynamics and the accurate phenomenology of the alkaline electrolyzers reported in David et al. (2020), a reduced model able to be used as a control-oriented model is obtained and a fuel cell. In this way, the additional electrical energy produced in the power sources, so it is beyond the scope of this paper. Details on this topic can be found in Milewski et al. (2014); Sánchez et al. (2020); Speckmann et al. (2019).

The remainder of the paper is structured as follows. A detailed description of a high-pressure alkaline electrolyzer is presented in Section 2. Next, in Section 3, an optimal model-based controller is designed. Simulation results are presented and discussed in Section 4. Finally, some concluding remarks are gathered in Section 5.

2. HIGH-PRESSURE ALKALINE ELECTROLYZER

The main contribution of this paper is twofold. First, from a well-established nonlinear model considering the dynamics and the accurate phenomenology of the alkaline electrolyzers reported in David et al. (2020), a reduced model able to be used as a control-oriented model is obtained and properly validated by using the complete nonlinear model (which, in turn, is validated with real data). Second, by using the reduced model, an optimal controller is designed and the closed-loop performance of the system is evaluated based on the maximization of the hydrogen purity through the mitigation of the cross-contamination of gases into the chambers.

The main goal of this paper is to separate water into \( \text{H}_2 \) and \( \text{O}_2 \) and to use this energy source in the fuel cell, which is the subject of the next paragraph. In this process, it is highly important to minimize the diffusion through the membrane caused by differences in both concentration and pressure. Up to 2% of \( \text{H}_2 \) in the \( \text{O}_2 \) stream is widely accepted as a limit, taking into account that the lower explosive limit of \( \text{H}_2 \) is 4%. Additionally, \( \text{H}_2 \) and \( \text{O}_2 \) gases must be delivered at high pressures in order to avoid the use of compressors. Since gas purity decreases with higher pressures, it is expected to increase the possible operating pressure preventing contamination with a suitable control strategy.

As previously mentioned, a proposed solution for energy storage is the combination of an electrolyzer, storage tanks and a fuel cell. In this way, the additional electrical energy is used to produce hydrogen that is stored in the tanks. When renewable energy sources are not able to meet the demand, the stored hydrogen is consumed by the fuel cell. The components of this system are:

- a pressurized tank (PT) that contains a pack of 15 alkaline electrolytic cells;
- two independent KOH solution circuits with recirculation pumps;
- two gas separation chambers (SC) where the produced gas is split from the liquid KOH solution;
- two heat exchangers for both circuits (HEO and HEH);
- a water injection pump that periodically replenishes the consumed water;
- two outlet lines controlled by two motorized valves (MVO and MVH) connected to storage tanks; and
- an equalization line that connects both bottoms of the SCs.

A detailed description of this system is presented in David et al. (2019a, 2020).
capacity of 0.5 Nm$^3$/h, needle-type outlet valves with a relatively small maximum flow coefficient, e.g., $C_v = 0.004$, must be used. In order to be able to control the system with only one valve per outlet line, the pressure in both storage tanks should be similar.

Another variable to be controlled is the difference between the liquid levels in both SCs, defined as

$$\Delta L = L_{H_2} - L_{O_2}. \quad (4)$$

This variable must be kept around a set-point $\Delta L_{ref} = 0$. This condition will contribute to the natural action of the equalization line circuit by keeping the pressure equalized on both sides of the membrane. In other words, if the control dynamics are slow enough, the equalization line ensures that the pressure in both SCs is almost the same, and the same happens in the electrolytic cells. As stated by Schalenbach et al. (2018), the Zirfon$^\text{TM}$ membrane is highly permeable to pressure differences. Finally, controlling the difference in level and pressure generates a high purity of the supplied gases. However, the absence of contamination is unreachable due to the natural diffusion that occurs in the studied process.

The control scheme proposed to achieve the objectives is presented in Figure 2. The controller produces two valve opening values, $u_{H_2}$ and $u_{O_2}$, taking values between 0 (minimum opening) and 10 (maximum opening). The control values are computed to ensure that

$$P_{H_2} \rightarrow P_{ref}, \quad \Delta L \rightarrow 0.$$

In normal operation, this pressure is set externally in order to follow smoothly the pressure of the storage tanks $P_{tank}$. Accordingly, the reference for the pressure $P_{ref}$ is defined as

$$P_{ref} = P_{tank} + P_{gap}, \text{ subject to } |dP_{ref}/dt| <\alpha. \quad (5)$$

being $\alpha$ a rate limit in kPa/s. This rate limit ensures that a sudden change in the storage pressure does not generate an excessive variation in the pressure at both sides of the membrane, with the consequent cross-contamination. Under the assumption of similar pressures, $P_{tank}$ is set equal to $P_{H_2}$. Moreover, the pressure gap between $P_{ref}$ and $P_{tank}$, $P_{gap} = 50$ kPa, is needed to compensate the action of the retention valves (RVO and RVH).

2.2 Reduced control-oriented model

A highly-detailed model for alkaline electrolyzers is given in David et al. (2019a, 2020). This model has 25 differential equations (i.e., 25 states) and 17 additional variables, 50 structural parameters and 49 functional parameters. Such a model is suitable for simulations but not for control design. For this purpose, those variables that produce smaller effects on the controlled variables ($\Delta L$ and $P_{H_2}$) might be neglected under some assumptions and guaranteed conditions that are explained next.

- Although the ultimate goal is to maximize the purity of the gases, the concentrations of impurities are not taken into account for the controller, which is based on the liquid levels and the system pressure.

</table>

- In addition, despite having two paths of diffusion, i.e., through the membrane and through the equalization line, the latter is smaller than the former. Then, the diffusion through the equalization line can be neglected along with the corresponding states.
- Moreover, under the hypothesis of reaching gas purities greater than 99%, saturation of pure gas in each cell can be assumed in order to calculate diffusion across the membrane.
- Furthermore, according to the ideal gas law, the gas moles behave equally no matter the substance, hence it only matters the accountancy of the number of moles at each line.
- Finally, only the concentrations of pure gases in the electrolytic cells and in the SCs can be considered.

Based on the previous assumptions, the model can be reduced to 14 states, which are listed in Table 1. The rest of the states are considered constant while the parameters, which are represented by algebraic equations, are not modified.

3. CONTROL DESIGN

In this section, a model-based \( H_{\infty} \) optimal controller is proposed for mitigating the cross-contamination of gases through the membrane in the alkaline electrolyzer presented in Section 2.

A linear model of the electrolyzer is required, therefore the operating conditions of the electrolyzer must be defined. Assuming the control objective of tracking \( P_{\text{ref}} \) given in (5) and the regulation of \( \Delta L \), around 0 are satisfied, the operating conditions can be parameterized by the steady-state values of the tank pressure \( P_{\text{tank}} \) and the current \( I \). Thus, the system operating region is defined as

\[
\mathcal{O} = \{ (P_{\text{tank}}, I) : 0 \text{ kPa} \leq P_{\text{tank}} \leq 7000 \text{ kPa} \text{ and } 10 \text{ A} \leq I \leq 50 \text{ A} \}. 
\]

Next, the reduced nonlinear model introduced in Section 2.2 is numerically linearized at a representative operating point \((P_{\text{tank}}, I) \in \mathcal{O}\). To select this point, the linearization is performed over a grid of operating points in \( \mathcal{O} \). The magnitude of the frequency responses for these operating points is shown in Figure 3 in gray lines and the selected nominal model is represented by a thicker blue line. This latter model will be used to design the considered linear controllers.

The selected nominal dynamics are approximately by the model

\[
y(s) = G(s) \begin{bmatrix} \hat{I}(s) \\ \hat{\tilde{u}}(s) \end{bmatrix} = \begin{bmatrix} G_d(s) & G_c(s) \end{bmatrix} \begin{bmatrix} \hat{I}(s) \\ \hat{\tilde{u}}(s) \end{bmatrix},
\]

where

\[
\hat{\tilde{u}} = \begin{bmatrix} \hat{u}_{H_2} \\ \hat{u}_{O_2} \end{bmatrix} = \begin{bmatrix} u_{H_2} - \bar{u}_{H_2} \\ u_{O_2} - \bar{u}_{O_2} \end{bmatrix}, \quad y = \begin{bmatrix} P_{H_2} - \bar{P}_{H_2} \\ \Delta L \end{bmatrix}.
\]

The variable \( \hat{\tilde{u}} \) is the vector of control inputs, and \( y \) is the vector of the controlled variables. The incremental current \( \hat{I} = I - \bar{I} \) acts as a disturbance to be rejected. All of these variables are incremental values with respect to \( \bar{I}, \bar{u}_{H_2}, \bar{u}_{O_2}, \) and \( \bar{P}_{H_2} \), where the last three variables are functions of the operating point \((P_{\text{tank}}, \bar{I})\).

The controller can be designed in the frame of multi-variable optimal control. In this case, the control design objectives are expressed as

\[
\min_{K(s)} \| z \|_2, \quad \text{subject to } \| w \|_2
given \text{that } z \text{ is a performance variable and } w \text{ a disturbance. Therefore, the controller design consists in defining a control setup and in selecting } z \text{ and } w \text{ according to the control specifications with suitable weighting functions (Sánchez-Peña and Sznaier, 1998).}

In the electrolyzer case, tracking a pressure reference \( P_{\text{ref}} \) while rejecting the disturbance \( I \) is sought. Hence, the performance variable \( z \) represents the pressure and level errors, and the disturbance \( w \), of the system pressure and the current, i.e.,

\[
z = W_{\epsilon}(s) M(s) \begin{bmatrix} P_{H_2} - P_{\text{ref}} \\ \Delta L \end{bmatrix}, \quad w = W_u(s) \begin{bmatrix} P_{\text{ref}} \\ I \end{bmatrix},
\]

where

\[
M(s) = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad W_{\epsilon}(s) = \begin{bmatrix} k_{\epsilon,1} & 0 \\ 0 & k_{\epsilon,2} \end{bmatrix},
\]

\[
W_u(s) = \begin{bmatrix} k_{u,1} & 0 \\ 0 & k_{u,2} \end{bmatrix} \frac{s/0.1\omega_c + 1}{s/10k_{\epsilon,1} + 1},
\]

being \( k_{\epsilon,j}, k_{u,j} \) and \( \omega_c \) design parameters. The weighting function \( M(s)W_{\epsilon}(s) \) penalizes the low frequencies of the
pressure and level errors and $W_\omega(s)$ penalizes the magnitude at high frequencies of the control actions. The closed-loop setup is shown in Figure 4.

The final controller is obtained after solving the optimization problem (7) and left-multiplying the resulting $\hat{K}(s)$ by $M(s)$, that is,

$$K_\infty(s) = M(s)\hat{K}(s).$$

This factorization is needed to ensure the existence of a stabilizing controller.

The order of the controller will be the order of the nominal model plus the order of all the weighting functions. Therefore, to simplify the real-time implementation, the order of $G(s)$ can be numerically reduced. The nominal model of the system to be controlled, namely as $G_c(s)$, exhibits a frequency response similar to a first-order system for each channel. Therefore, using balanced truncation model reduction (Glover, 1984), the plant is approximated by a second order system. The full and reduced models are compared in Figure 5.

4. SIMULATION RESULTS

Numerical simulations were performed with the previously designed controller closing the loop with the full-nonlinear model of the electrolyzer. For comparison purposes, a pair of decoupled PI controllers were also designed. For decoupling the loops, the plant was right-multiplied by the inverse of its DC-gain (Aström and Hägglund, 2006), that is,

$$G_{\text{dec}}(s) = G_c(s)G_c(0)^{-1}.$$ 

Moreover, the parameters of the PI controllers were:

$$k_{i,1} = 0.18, \quad k_{p,1} = 3, \quad k_{i,2} = 0.16, \quad k_{p,2} = 200.$$ 

For the $H_\infty$ controller, the design parameters in the weighting functions were set as

$$k_{e,1} = 0.1, \quad k_{e,2} = 4, \quad k_{u,1} = 0.8, \quad k_{u,1} = 0.8,$$

and $\omega_c = 0.7 \text{ rad/s}$.

To evaluate the proposed controller, a scenario in which the electrolyzer produces gases at constant pressure but the electric current fluctuates, as if it was provided by renewable energy sources. The resulting simulation using the designed controllers can be seen in Figure 6. As can be noted, both controllers manage to maintain the pressure $P_{\text{H}_2}$ close to the reference $P_{\text{ref}}$, with a maximum error of 0.5%, and the level difference in less than 2 mm. Because of this, the $O_2$ impurity, that is always the highest value, is below 1%. For this particular scenario, the PI controller shows a slightly smaller regulation errors in long term, but the $H_\infty$ control converges to zero faster that in the PI case after a current change. The performance achieved by both controllers depends on the tuning parameters, the gains in the PI case and the weighting function in the $H_\infty$ control. The PI controller might be more attractive to practical engineers as it is based on a more intuitive SISO tuning procedure. Nevertheless, this method relies on non-perfect decoupling that can affect the final closed-loop performance. On the other hand, although the $H_\infty$ controller relies on more sophisticated design tools, it is designed directly and systematically from the MIMO model with less approximations, which could results in a more robust closed-loop system and less design iterations.

5. CONCLUSIONS

In the quest to raise the operating pressure of alkaline electrolyzers, control strategies are needed to decrease gas cross-contamination and, consequently, increase the purity of the supplied gases. In that sense, modelling and control are key issues in operation and design improvements. This work presents a multi-input multi-output optimal controller that was tested in closed loop with a high-fidelity nonlinear model of the electrolyzer. It was able to maintain impurity below 1% in all cases, keeping the liquid solution level difference between both SCs below 4mm and a maximum pressure error of 0.5%.

ACKNOWLEDGEMENTS

This work has been partially funded by the DEOCS project (DPI2016-76493-C3-3R).
